# PROPERTIES OF THE ROBIN'S INEQUALITY 

FRANK VEGA

#### Abstract

In mathematics, the Riemann hypothesis is a conjecture that the Riemann zeta function has its zeros only at the negative even integers and complex numbers with real part $\frac{1}{2}$. Many consider it to be the most important unsolved problem in pure mathematics. The Robin's inequality consists in $\sigma(n)<e^{\gamma} \times n \times \ln \ln n$ where $\sigma(n)$ is the divisor function and $\gamma \approx 0.57721$ is the Euler-Mascheroni constant. The Robin's inequality is true for every natural number $n>5040$ if and only if the Riemann hypothesis is true. We prove the Robin's inequality is true for every natural number $n>5040$ when $15 \nmid n$, where $15 \nmid n$ means that $n$ is not divisible by 15 . More specifically: every counterexample should be divisible by $2^{20} \times 3^{13} \times 5^{8} \times k_{1}$ or either $2^{20} \times 3^{13} \times k_{2}$ or $2^{20} \times 5^{8} \times k_{3}$, where $k_{1}, k_{2}, k_{3}>1,2 \nmid k_{1}, 3 \nmid k_{1}, 5 \nmid k_{1}$, $2 \nmid k_{2}, 3 \nmid k_{2}, 2 \nmid k_{3}$ and $5 \nmid k_{3}$.

## 1. Introduction

In mathematics, the Riemann hypothesis is a conjecture that the Riemann zeta function has its zeros only at the negative even integers and complex numbers with real part $\frac{1}{2}$. Many consider it to be the most important unsolved problem in pure mathematics [3]. It is of great interest in number theory because it implies results about the distribution of prime numbers [3]. It was proposed by Bernhard Riemann (1859), after whom it is named [3]. It is one of the seven Millennium Prize Problems selected by the Clay Mathematics Institute to carry a US $1,000,000$ prize for the first correct solution [3]. The divisor function $\sigma(n)$ for a natural number $n$ is defined as the sum of the powers of the divisors of $n$,

$$
\sigma(n)=\sum_{k \mid n} k
$$

where $k \mid n$ means that the natural number $k$ divides $n$ [5]. In 1915, Ramanujan proved that under the assumption of the Riemann hypothesis, the inequality,

$$
\sigma(n)<e^{\gamma} \times n \times \ln \ln n
$$

holds for all sufficiently large $n$, where $\gamma \approx 0.57721$ is the Euler-Mascheroni constant [2]. The largest known value that violates the inequality is $n=5040$. In 1984, Guy Robin proved that the inequality is true for all $n>5040$ if and only if the Riemann hypothesis is true [2]. Using this inequality, we show an interesting result.

[^0]
## 2. Results

Theorem 2.1. Given a natural number $n=p_{1}^{a_{1}} \times p_{2}^{a_{2}} \times \ldots \times p_{m}^{a_{m}}$ such that $p_{1}, p_{2}, \ldots, p_{m}$ are prime numbers, then we obtain the following inequality

$$
\frac{\sigma(n)}{n}<\prod_{i=1}^{m} \frac{p_{i}}{p_{i}-1}
$$

Proof. For a natural number $n=p_{1}^{a_{1}} \times p_{2}^{a_{2}} \times \ldots \times p_{m}^{a_{m}}$ such that $p_{1}, p_{2}, \ldots, p_{m}$ are prime numbers, then we obtain the following formula

$$
\begin{equation*}
\sigma(n)=\prod_{i=1}^{m} \frac{p_{i}^{a_{i}+1}-1}{p_{i}-1} \tag{2.1}
\end{equation*}
$$

from the Ramanujan's notebooks [1]. In this way, we have that

$$
\begin{equation*}
\frac{\sigma(n)}{n}=\prod_{i=1}^{m} \frac{p_{i}^{a_{i}+1}-1}{p_{i}^{a_{i}} \times\left(p_{i}-1\right)} . \tag{2.2}
\end{equation*}
$$

However, for any prime power $p_{i}^{a_{i}}$, we have that

$$
\frac{p_{i}^{a_{i}+1}-1}{p_{i}^{a_{i}} \times\left(p_{i}-1\right)}<\frac{p_{i}^{a_{i}+1}}{p_{i}^{a_{i}} \times\left(p_{i}-1\right)}=\frac{p_{i}}{p_{i}-1} .
$$

Consequently, we obtain that

$$
\begin{equation*}
\frac{\sigma(n)}{n}<\prod_{i=1}^{m} \frac{p_{i}}{p_{i}-1} \tag{2.3}
\end{equation*}
$$

Theorem 2.2. Given some prime numbers $p_{1}, p_{2}, \ldots, p_{m}$, then we obtain the following inequality,

$$
\prod_{i=1}^{m} \frac{p_{i}}{p_{i}-1}<\frac{\pi^{2}}{6} \times \prod_{i=1}^{m} \frac{p_{i}+1}{p_{i}}
$$

Proof. Given a prime number $p_{i}$, we obtain that

$$
\frac{p_{i}}{p_{i}-1}=\frac{p_{i}^{2}}{p_{i}^{2}-p_{i}}
$$

and that would be equivalent to

$$
\frac{p_{i}^{2}}{p_{i}^{2}-p_{i}}=\frac{p_{i}^{2}}{p_{i}^{2}-1-\left(p_{i}-1\right)}
$$

and that is the same as

$$
\frac{p_{i}^{2}}{p_{i}^{2}-1-\left(p_{i}-1\right)}=\frac{p_{i}^{2}}{\left(p_{i}-1\right) \times\left(\frac{p_{i}^{2}-1}{\left(p_{i}-1\right)}-1\right)}
$$

which is equal to

$$
\frac{p_{i}^{2}}{\left(p_{i}-1\right) \times\left(\frac{p_{i}^{2}-1}{\left(p_{i}-1\right)}-1\right)}=\frac{p_{i}^{2}}{\left(p_{i}-1\right) \times \frac{p_{i}^{2}-1}{\left(p_{i}-1\right)} \times\left(1-\frac{\left(p_{i}-1\right)}{p_{i}^{2}-1}\right)}
$$

that is equivalent to

$$
\frac{p_{i}^{2}}{\left(p_{i}-1\right) \times \frac{p_{i}^{2}-1}{\left(p_{i}-1\right)} \times\left(1-\frac{\left(p_{i}-1\right)}{p_{i}^{2}-1}\right)}=\frac{p_{i}^{2}}{p_{i}^{2}-1} \times \frac{1}{1-\frac{\left(p_{i}-1\right)}{p_{i}^{2}-1}}
$$

which is the same as

$$
\frac{p_{i}^{2}}{p_{i}^{2}-1} \times \frac{1}{1-\frac{\left(p_{i}-1\right)}{p_{i}^{2}-1}}=\frac{1}{1-p_{i}^{-2}} \times \frac{1}{1-\frac{1}{\left(p_{i}+1\right)}}
$$

and finally

$$
\frac{1}{\left(1-p_{i}^{-2}\right)} \times \frac{1}{1-\frac{1}{\left(p_{i}+1\right)}}=\frac{1}{\left(1-p_{i}^{-2}\right)} \times \frac{p_{i}+1}{p_{i}} .
$$

In this way, we have that

$$
\prod_{i=1}^{m} \frac{p_{i}}{p_{i}-1}=\prod_{i=1}^{m} \frac{1}{1-p_{i}^{-2}} \times \prod_{i=1}^{m} \frac{p_{i}+1}{p_{i}}
$$

However, we know that

$$
\prod_{i=1}^{m} \frac{1}{1-p_{i}^{-2}}<\prod_{j=1}^{\infty} \frac{1}{1-p_{j}^{-2}}
$$

where $p_{j}$ is the $j^{\text {th }}$ prime number and we have that

$$
\prod_{j=1}^{\infty} \frac{1}{1-p_{j}^{-2}}=\frac{\pi^{2}}{6}
$$

as a consequence of the result in the Basel problem [5]. Consequently, we obtain that

$$
\begin{equation*}
\prod_{i=1}^{m} \frac{p_{i}}{p_{i}-1}<\frac{\pi^{2}}{6} \times \prod_{i=1}^{m} \frac{p_{i}+1}{p_{i}} \tag{2.4}
\end{equation*}
$$

Definition 2.3. We recall that an integer $n$ is said to be squarefree if for every prime divisor $p$ of $n$ we have $p^{2} \nmid n$, where $p^{2} \nmid n$ means that $p^{2}$ does not divide $n$ [2].
Theorem 2.4. Given a squarefree number $n=q_{1} \times \ldots \times q_{m}$ such that $q_{1}, q_{2}, \ldots, q_{m}$ are odd prime numbers, $3 \nmid n$ and $5 \nmid n$, then we obtain the following inequality

$$
\begin{equation*}
\frac{\pi^{2}}{6} \times \frac{3}{2} \times \sigma(n) \leq e^{\gamma} \times n \times \ln \ln \left(2^{19} \times n\right) \tag{2.5}
\end{equation*}
$$

Proof. This proof is very similar with the demonstration in Theorem 1.1 from the article reference [2]. By induction with respect to $\omega(n)$, that is the number of distinct prime factors of $n[2]$. Put $\omega(n)=m[2]$. We need to prove the assertion for those integers with $m=1$. From the equation (2.1), we obtain that

$$
\begin{equation*}
\sigma(n)=\left(q_{1}+1\right) \times\left(q_{2}+1\right) \times \ldots \times\left(q_{m}+1\right) \tag{2.6}
\end{equation*}
$$

when $n=q_{1} \times q_{2} \times \ldots \times q_{m}$. In this way, for any prime number $p_{i} \geq 7$, then we need to prove

$$
\begin{equation*}
\frac{\pi^{2}}{6} \times \frac{3}{2} \times\left(1+\frac{1}{p_{i}}\right) \leq e^{\gamma} \times \ln \ln \left(2^{19} \times p_{i}\right) . \tag{2.7}
\end{equation*}
$$

For $p_{i}=7$, we have that

$$
\frac{\pi^{2}}{6} \times \frac{3}{2} \times\left(1+\frac{1}{7}\right) \leq e^{\gamma} \times \ln \ln \left(2^{19} \times 7\right)
$$

is actually true. For another prime number $p_{i}>7$, we have that

$$
\left(1+\frac{1}{p_{i}}\right)<\left(1+\frac{1}{7}\right)
$$

and

$$
e^{\gamma} \times \ln \ln \left(2^{19} \times 7\right)<e^{\gamma} \times \ln \ln \left(2^{19} \times p_{i}\right)
$$

which clearly implies that the inequality (2.7) is true for every prime number $p_{i} \geq 7$. Now, suppose it is true for $m-1$, with $m \geq 2$ and let us consider the assertion for those squarefree $n$ with $\omega(n)=m$ [2]. So let $n=q_{1} \times \ldots \times q_{m}$ be a squarefree number and assume that $q_{1}<\ldots<q_{m}$ for $q_{m} \geq 7$.

Case $1: q_{m} \geq \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}\right)=\ln \left(2^{19} \times n\right)$.
By the induction hypothesis we have
$\frac{\pi^{2}}{6} \times \frac{3}{2} \times\left(q_{1}+1\right) \times \ldots \times\left(q_{m-1}+1\right) \leq e^{\gamma} \times q_{1} \times \ldots \times q_{m-1} \times \ln \ln \left(2^{19} \times q_{1} q_{1} \times \ldots \times q_{m-1}\right)$ and hence

$$
\begin{gathered}
\frac{\pi^{2}}{6} \times \frac{3}{2} \times\left(q_{1}+1\right) \times \ldots \times\left(q_{m-1}+1\right) \times\left(q_{m}+1\right) \leq \\
e^{\gamma} \times q_{1} \times \ldots \times q_{m-1} \times\left(q_{m}+1\right) \times \ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right)
\end{gathered}
$$

when we multiply the both sides of the inequality by $\left(q_{m}+1\right)$. We want to show that

$$
e^{\gamma} \times q_{1} \times \ldots \times q_{m-1} \times\left(q_{m}+1\right) \times \ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right) \leq
$$

$e^{\gamma} \times q_{1} \times \ldots \times q_{m-1} \times q_{m} \times \ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}\right)=e^{\gamma} \times n \times \ln \ln \left(2^{19} \times n\right)$.
Indeed the previous inequality is equivalent with

$$
q_{m} \times \ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}\right) \geq\left(q_{m}+1\right) \times \ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right)
$$

or alternatively

$$
\begin{gathered}
\frac{q_{m} \times\left(\ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}\right)-\ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right)\right)}{\ln q_{m}} \geq \\
\frac{\ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right)}{\ln q_{m}}
\end{gathered}
$$

From the reference [2], we have that if $0<a<b$, then

$$
\begin{equation*}
\frac{\ln b-\ln a}{b-a}=\frac{1}{(b-a)} \int_{a}^{b} \frac{d t}{t}>\frac{1}{b} . \tag{2.8}
\end{equation*}
$$

We can apply the inequality (2.8) to the previous one just using $b=\ln \left(2^{19} \times q_{1} \times\right.$ $\left.\ldots \times q_{m-1} \times q_{m}\right)$ and $a=\ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right)$. Certainly, we have that

$$
\begin{gathered}
\ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}\right)-\ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right)= \\
\ln \frac{2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}}{2^{19} \times q_{1} \times \ldots \times q_{m-1}}=\ln q_{m} .
\end{gathered}
$$

In this way, we obtain that

$$
\frac{q_{m} \times\left(\ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}\right)-\ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right)\right)}{\ln q_{m}}>
$$

$$
\frac{q_{m}}{\ln \left(2^{19} \times q_{1} \times \ldots \times q_{m}\right)}
$$

Using this result we infer that the original inequality is certainly satisfied if the next inequality is satisfied

$$
\frac{q_{m}}{\ln \left(2^{19} \times q_{1} \times \ldots \times q_{m}\right)} \geq \frac{\ln \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1}\right)}{\ln q_{m}}
$$

which is trivially true for $q_{m} \geq \ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}\right)$ [2].
Case $2: q_{m}<\ln \left(2^{19} \times q_{1} \times \ldots \times q_{m-1} \times q_{m}\right)=\ln \left(2^{19} \times n\right)$.
We need to prove

$$
\frac{\pi^{2}}{6} \times \frac{3}{2} \times \frac{\sigma(n)}{n} \leq e^{\gamma} \times \ln \ln \left(2^{19} \times n\right) .
$$

We know that $\frac{3}{2}<1.6=\frac{4 \times 6}{3 \times 5}$. Nevertheless, we could have that

$$
\frac{3}{2} \times \frac{\sigma(n)}{n} \times \frac{\pi^{2}}{6}<\frac{4 \times 6 \times \sigma(n)}{3 \times 5 \times n} \times \frac{\pi^{2}}{6}=\frac{\sigma(3 \times 5 \times n)}{3 \times 5 \times n} \times \frac{\pi^{2}}{6} \leq e^{\gamma} \times \ln \ln \left(2^{19} \times n\right)
$$

where this is possible because of $3 \nmid n$ and $5 \nmid n$. If we apply the logarithm to the both sides of the inequality, then we obtain that

$$
\begin{aligned}
\ln \left(\frac{\pi^{2}}{6}\right)+(\ln (3+1)-\ln 3) & +(\ln (5+1)-\ln 5)+\sum_{j=i}^{m}\left(\ln \left(q_{j}+1\right)-\ln q_{j}\right) \leq \\
\gamma & +\ln \ln \ln \left(2^{19} \times n\right) .
\end{aligned}
$$

From the reference [2], we note that

$$
\ln \left(p_{1}+1\right)-\ln p_{1}=\int_{p_{1}}^{p_{1}+1} \frac{d t}{t}<\frac{1}{p_{1}}
$$

In addition, note also that $\ln \left(\frac{\pi^{2}}{6}\right)<\frac{1}{2}$. It is enough to prove that

$$
\frac{1}{2}+\frac{1}{3}+\frac{1}{5}+\frac{1}{q_{1}}+\ldots+\frac{1}{q_{m}} \leq \sum_{p \leq q_{m}} \frac{1}{p} \leq \gamma+\ln \ln \ln \left(2^{19} \times n\right)
$$

where $p \leq q_{m}$ means all the prime lesser than or equal to $q_{m}$. However, we know that

$$
\gamma+\ln \ln q_{m}<\gamma+\ln \ln \ln \left(2^{19} \times n\right)
$$

since $q_{m}<\ln \left(2^{19} \times n\right)$ and therefore, we would only need to prove that

$$
\sum_{p \leq q_{m}} \frac{1}{p} \leq \gamma+\ln \ln q_{m}
$$

which is true according to the Lemma 2.1 from the article reference [2]. In this way, we finally show the Theorem is indeed satisfied.

Theorem 2.5. Given a natural number $n=2^{a_{1}} \times 3^{a_{2}} \times 5^{a_{3}}>5040$ such that $a_{1}, a_{2}, a_{3} \geq 0$ are integers, then the Robin's inequality is true for $n$.

Proof. Given a natural number $n=p_{1}^{a_{1}} \times p_{2}^{a_{2}} \times \ldots \times p_{m}^{a_{m}}>5040$ such that $p_{1}, p_{2}, \ldots, p_{m}$ are prime numbers, we need to prove that

$$
\frac{\sigma(n)}{n}<e^{\gamma} \times \ln \ln n
$$

that would be the same as

$$
\begin{equation*}
\prod_{i=1}^{m} \frac{p_{i}}{p_{i}-1}<e^{\gamma} \times \ln \ln n \tag{2.9}
\end{equation*}
$$

according to Theorem 2.1. Given a natural number $n=2^{a_{1}} \times 3^{a_{2}} \times 5^{a_{3}}>5040$ such that $a_{1}, a_{2}, a_{3} \geq 0$ are integers, we have that

$$
\prod_{i=1}^{m} \frac{p_{i}}{p_{i}-1} \leq \frac{2 \times 3 \times 5}{1 \times 2 \times 4}=3.75<e^{\gamma} \times \ln \ln (5040) \approx 3.81
$$

However, we know for $n>5040$, we have that

$$
e^{\gamma} \times \ln \ln (5040)<e^{\gamma} \times \ln \ln n
$$

and thus, the proof is completed.
Theorem 2.6. The Robin's inequality is true for every natural number $n>5040$ when $15 \nmid n$. More specifically: every counterexample should be divisible by $2^{20} \times$ $3^{13} \times 5^{8} \times k_{1}$ or either $2^{20} \times 3^{13} \times k_{2}$ or $2^{20} \times 5^{8} \times k_{3}$, where $k_{1}, k_{2}, k_{3}>1,2 \nmid k_{1}$, $3 \nmid k_{1}, 5 \nmid k_{1}, 2 \nmid k_{2}, 3 \nmid k_{2}, 2 \nmid k_{3}$ and $5 \nmid k_{3}$.
Proof. Given a natural number $n=p_{1}^{a_{1}} \times p_{2}^{a_{2}} \times \ldots \times p_{m}^{a_{m}}>5040$ such that $p_{1}, p_{2}, \ldots, p_{m}$ are prime numbers, then we will check the Robin's inequality for $n$. We know this true when the greatest prime divisor of $n$ is lesser than or equal to 5 according to Theorem 2.5. Another case is when $3 \nmid n$ and $5 \nmid n$. We need to prove the inequality (2.9) for that case. In addition, the inequality (2.9) would be true when

$$
\frac{\pi^{2}}{6} \times \prod_{i=1}^{m} \frac{p_{i}+1}{p_{i}}<e^{\gamma} \times \ln \ln n
$$

according to the Theorem 2.2. Using the properties of the equation (2.2), we obtain that will be equivalent to

$$
\frac{\pi^{2}}{6} \times \frac{\sigma\left(n^{\prime}\right)}{n^{\prime}}<e^{\gamma} \times \ln \ln n
$$

where $n^{\prime}=q_{1} \times \ldots \times q_{m}$ is the squarefree representation of $n$. However, the Robin's inequality has been proved for all integers $n$ not divisible by 2 (which are bigger than 10) [2]. Hence, we need to prove when $2 \mid n^{\prime}$. In addition, we know the Robin's inequality is true for every $n>5040$ such that $2^{k} \mid n$ for $1 \leq k \leq 19$ [4]. Consequently, we only need to prove that for all $n>5040$ such that $2^{20} \mid n$ and thus, we have that

$$
e^{\gamma} \times n^{\prime} \times \ln \ln \left(2^{19} \times \frac{n^{\prime}}{2}\right)<e^{\gamma} \times n^{\prime} \times \ln \ln n
$$

because of $2^{19} \times \frac{n^{\prime}}{2}<n$ when $2^{20} \mid n$ and $2 \mid n^{\prime}$. In this way, we only need to prove that

$$
\frac{\pi^{2}}{6} \times \sigma\left(n^{\prime}\right) \leq e^{\gamma} \times n^{\prime} \times \ln \ln \left(2^{19} \times \frac{n^{\prime}}{2}\right)
$$

According to the equation (2.6) and $2 \mid n^{\prime}$, we have that

$$
\frac{\pi^{2}}{6} \times 3 \times \sigma\left(\frac{n^{\prime}}{2}\right) \leq e^{\gamma} \times 2 \times \frac{n^{\prime}}{2} \times \ln \ln \left(2^{19} \times \frac{n^{\prime}}{2}\right)
$$

which is the same as

$$
\frac{\pi^{2}}{6} \times \frac{3}{2} \times \sigma\left(\frac{n^{\prime}}{2}\right) \leq e^{\gamma} \times \frac{n^{\prime}}{2} \times \ln \ln \left(2^{19} \times \frac{n^{\prime}}{2}\right)
$$

which is true according to the Theorem 2.4. In addition, we know the Robin's inequality is true for every $n>5040$ such that $3^{i} \mid n$ and $5^{j} \mid n$ for $1 \leq i \leq 12$ and $1 \leq j \leq 7$ [4]. To sum up, we have finally proved this result.
